Control Flow Structures

Control Flow

There are many times where you don't just want to execute one statement after another: you need to control the flow of execution.

Main Idea

Execute some code when
a condition is fulfilled

Control Flow Structures

- if-then-else
- switch cases
- repeat loop
- while loop
- for loop

If-Then-Else

If-Then-Else

If-then-else statements make it possible to choose between two (possibly compound) expressions depending on the value of a **logical** condition.

```r
# absolute value
num <- rnorm(1)
if (num >= 0) {
  num
} else {
  -num
}

## [1] 0.05950904
```

If-Then-Else

If-then-else statements make it possible to choose between two (possibly compound) expressions depending on the value of a **logical** condition.

```
if (condition) expression1 else expression2
```

If condition is true then expression1 is evaluated otherwise expression2 is executed

If-Then-Else

If-then-else with **simple** expressions (equivalent forms):

```
# simple expressions don't require braces
if (condition) expression1 else expression2

# it's good practice to use braces, even with simple expressions
if (condition) {
  expression1
} else {
  expression2
}
```

If-Then-Else

Equivalent forms:

```
# simple if-then-else
if (5 > 2) 5 * 2 else 5 / 2

# simple if-then-else
if (5 > 2) {
  5 * 2
} else {
  5 / 2
}
```

If-Then-Else

If-then-else with **compound** expressions:

```
# compound expressions require braces
if (condition) {
  expression1
  expression2
  ...
} else {
  expression3
  expression4
  ...
}
```

Example: If-Then-Else

Equivalent forms:

```
# simple if-then-else
if (5 > 2) 5 * 2 else 5 / 2

## [1] 10

# simple if-then-else
if (5 > 2) {
  5 * 2
} else {
  5 / 2
}

## [1] 10
```

If-Then-Else

- `if()` takes a **logical** condition
- the condition must be a logical value **of length one**
- it executes the next statement if the condition is true
- if the condition is false, then it executes the false expression

2 types of If conditions

if-then-else

```
# if and else
if (condition) {
  expression_true
} else {
  expression_false
}
```

Just if

```
# simple if
if (condition) {
  expression_true
}
```

It is also possible to just have the if clause (without else)

Just If

Just `if`

```
# just if
if (condition) {
  expression1
  ...
}
```

Equivalent to:

```
# just if (else NULL)
if (condition) {
  expression1
  ...
} else NULL
```

If and Else

- `if()` takes a **logical** condition
- the condition must be a logical value of length one
- it executes the next statement if the condition is true
- if the condition is false, and there is no `else`, then it stops
- if the condition is false, and there is an `else`, then it executes the false expression

operation	usage
less than	x < x
greater than	x > y
less than or equal	x <= y
greater than or equal	x >= y
equality	x == y
different	x != y

Comparison operators produce logical values

Reminder of Logical Operators

operation	usage
NOT	`!x`
AND (elementwise)	`x & y`
AND (1st element)	`x && y`
OR (elementwise)	`x	y`
OR (1st element)	`x || y`
exclusive OR	`xor(x, y)`

Logical operators produce logical values

Just `if`'s behavior

```
# this prints
if (TRUE) {
  print("It is true")
}

# this does not print
if (FALSE) {
  print("It is false")
}
```

```
# this does not print
if (!TRUE) {
  print("It is not true")
}

# this prints
if (!FALSE) {
  print("It is not false")
}
```

Just if

```r
x <- 7

if (x >= 0) {
  print("it is positive")
}
```

```
## [1] "it is positive"
```

```r
if (is.numeric(x)) {
  print("it is numeric")
}
```

```
## [1] "it is numeric"
```

If and Else

```
y <- -5

if (y >= 0) {
  print("it is positive")
} else {
  print("it is negative")
}

## [1] "it is negative"
```

The else statement must occur on the same line as the closing brace from the if clause!

If and Else

The logical condition must be of length one!

```
if (c(TRUE, TRUE)) {
  print("it is positive")
} else {
  print("it is negative")
}

## Warning in if (c(TRUE, TRUE)) {:  the condition has
length > 1 and only the first element will be used

## [1] "it is positive"
```

If and Else

What's the length of the logical condition?

```r
x <- 3
y <- 4

if (x > 0 & y > 0) {
  print("they are not negative")
} else {
  print("they may be negative")
}

## [1] "they are not negative"
```

If and Else

If there's is a single statement, you can omit the braces:

```
if (TRUE) { print("It is true") }

if (TRUE) print("It is true")

# valid but not recommended
if (TRUE)
  print("It is true")
```

Equivalent ways

No braces:

```
# ok
if (TRUE) print("It's true")

# valid but not recommended
if (TRUE)
  print("It's true")
```

With braces:

```
# ok
if (TRUE) {print("It's true")}

# recommended
if (TRUE) {
  print("It's true")
}
```

If and Else

If there are multiple statements, you must use braces:

```
if (x > 0) {
  a <- x^(2)
  b <- 3 * a + 34.8 - exp(2)
}
```

Multiple If's

Multiple conditions can be defined by combining `if` and `else` repeatedly:

```
set.seed(9)
x <- round(rnorm(1), 1)

if (x > 0) {
  print("x is positive")
} else if (x < 0) {
  print("x is negative")
} else if (x == 0) {
  print("x is zero")
}

## [1] "x is negative"
```

Vectorized `ifelse()`

`if()` takes a single logical value. If you want to pass a logical vector of conditions, you can use `ifelse()`:

```
true_false <- c(TRUE, FALSE)

ifelse(true_false, "true", "false")

## [1] "true"  "false"
```

Vectorized If

```r
# some numbers
numbers <- c(1, 0, -4, 9, -0.9)

# are they non-negative or negative?
ifelse(numbers >= 0, "non-neg", "neg")

## [1] "non-neg" "non-neg" "neg"     "non-neg" "neg"
```

Test yourself

Which option will cause an error:

```
# A
if (is.numeric(1:5)) {
  print('ok')
}

# B
if ("TRUE") {
  print('ok')
}
```

```
# C
if (0) print('ok')

# D
if (NA) print('ok')

# E
if ('yes') {
  print('ok')
}
```

Function Switch

Multiple Selection with `switch()`

When a condition has multiple options, combining several `if` and `else` can become cumbersome

```r
first_name <- "harry"

if (first_name == "harry") {
  last_name <- "potter"
} else {
  if (first_name == "ron") {
    last_name <- "weasley"
  } else {
    if (first_name == "hermione") {
      last_name <- "granger"
    } else {
      last_name <- "not available"
    }
  }
}

last_name

## [1] "potter"
```

Multiple Selection with `switch()`

```r
first_name <- "ron"

last_name <- switch(
  first_name,
  harry = "potter",
  ron = "weasley",
  hermione = "granger",
  "not available")

last_name

## [1] "weasley"
```

Multiple Selection with `switch()`

- the `switch()` function makes it possible to choose between various alternatives
- `switch()` takes a character string
- followed by several named arguments
- `switch()` will match the input string with the provided arguments
- a default value can be given when there's no match
- multiple expression can be enclosed by braces

Multiple Selection with `switch()`

```
switch(expr,
       tag1 = rcode_block1,
       tag2 = rcode_block2,
       ...
       )
```

`switch()` selects one of the code blocks, depending on the value of expr

Multiple Selection with `switch()`

```r
operation <- "add"

result <- switch(
  operation,
  add = 2 + 3,
  product = 2 * 3,
  division = 2 / 3,
  other = {
    a <- 2 + 3
    exp(1 / sqrt(a))
  }
)

result

## [1] 5
```

Multiple Selection with `switch()`

- ▶ `switch()` can also take an integer as first argument
- ▶ in this case the remaining arguments do not need names
- ▶ instead, the they will have associated integers

```
switch(
  4,
  "one",
  "two",
  "three",
  "four")

## [1] "four"
```

Empty code blocks in `switch()`

Empty code blocks can be used to make several tags match the same code block:

```r
student <- "ron"

house <- switch(
  student,
  harry = ,
  ron = ,
  hermione = "gryffindor",
  draco = "slytherin")
```

In this case a value of `"harry"`, `"ron"` or `"hermione"` will cause `"gryffindor"`

Loops

About Loops

- Many times we need to perform a procedure several times

- The main idea is that of **iteration**

- For this purpose we use loops

- We perform operations as long as some condition is fulfilled

- R provides three basic paradigms:
  - for, repeat, while

For Loops

For Loops

Often we want to repeatedly carry out some computation a fixed number of times. For instance, repeat an operation for each element of a vector. In R this is done with a `for` loop

Motivation

Consider some numeric vector

```
prices <- c(2.50, 2.95, 3.45, 3.25)

prices

## [1] 2.50 2.95 3.45 3.25
```

Motivation

Say you want to display the prices on the console:

```
cat("Price 1 is", prices[1])
cat("Price 2 is", prices[2])
cat("Price 3 is", prices[3])
cat("Price 4 is", prices[4])
```

We are repeating the same operation four times

```
## Price 1 is 2.5
## Price 2 is 2.95
## Price 3 is 3.45
## Price 4 is 3.25
```

Motivation

We can use a `for` lope for this purpose:

```
for (i in 1:4) {
  cat("Price", i, "is", prices[i], "\n")
}

## Price 1 is 2.5
## Price 2 is 2.95
## Price 3 is 3.45
## Price 4 is 3.25
```

For Loops

`for` loops are used when we know exactly how many times we want the code to repeat

```
for (iterator in times) {
  do_something
}
```

`for` takes an *iterator* variable and a vector of *times* to iterate through

For Loops

```r
value <- 2

for (i in 1:5) {
  value <- value * 2
  print(value)
}

## [1] 4
## [1] 8
## [1] 16
## [1] 32
## [1] 64
```

For Loops

The vector of *times* does not have to be a numeric vector; it can be any vector

```
value <- 2
times <- c('1', '2', '3', '4', '5')

for (i in times) {
  value <- value * 2
  print(value)
}

## [1] 4
## [1] 8
## [1] 16
## [1] 32
## [1] 64
```

For Loops and Next statement

Sometimes we need to skip a loop iteration if a given condition is met, this can be done with a next statement

```
for (iterator in times) {
  expr1
  expr2
  if (condition) {
    next
  }
  expr3
  expr4
}
```

For Loops and Next statement

```r
x <- 2
for (i in 1:5) {
  y <- x * i
  if (y == 8) {
    next
  }
  print(y)
}

## [1] 2
## [1] 4
## [1] 6
## [1] 10
```

51

For Loops

For loop

```
# squaring values
x <- 1:5
y <- x

for (i in 1:5) {
  y[i] <- x[i]^2
}

y

## [1]  1  4  9 16 25
```

Vectorized computation

```
# squaring values
x <- 1:5
y <- x^2
y

## [1]  1  4  9 16 25
```

A less boring example

```r
# Generate a sample dataset (missing values as '-99')
set.seed(6354)
dat <- data.frame(
  replicate(6, sample(c(1:10, -99), 6, rep = TRUE))
)
names(dat) <- letters[1:6]

dat

##     a  b   c d  e  f
## 1   5  9   1 7  8 10
## 2   2  6  10 7  3  7
## 3  10  7   2 9 10  9
## 4   3  2 -99 4  5  6
## 5   8 10   3 3  3  5
## 6   4  5   2 3  1 10
```

A less boring example

```
# converting '-99' to NA's
dat$a[dat$a == -99] <- NA
dat$b[dat$b == -99] <- NA
dat$c[dat$c == -98] <- NA
dat$d[dat$d == -99] <- NA
dat$e[dat$e == -99] <- NA
dat$f[dat$g == -99] <- NA
```

With copy-and-paste it is easy to make mistakes. Can you spot
any mistakes?

A less boring example

```
# converting '-99' to NA's
dat$a[dat$a == -99] <- NA
dat$b[dat$b == -99] <- NA
dat$c[dat$c == -98] <- NA  # oops
dat$d[dat$d == -99] <- NA
dat$e[dat$e == -99] <- NA
dat$f[dat$g == -99] <- NA  # oops
```

A less boring example

```
# for loop to convert '-99' to NA's
columns <- letters[1:6]
for (j in columns) {
  dat[ ,j][dat[ ,j] == -99] <- NA
}

dat

##     a  b  c  d  e  f
## 1   5  9  1  7  8 10
## 2   2  6 10  7  3  7
## 3  10  7  2  9 10  9
## 4   3  2 NA  4  5  6
## 5   8 10  3  3  3  5
## 6   4  5  2  3  1 10
```

Nested Loops

It is common to have nested loops

```
for (iterator1 in times1) {
  for (iterator2 in times2) {
    expr1
    expr2
    ...
  }
}
```

Nested Loops

```r
# some matrix
A <- matrix(1:12, nrow = 3, ncol = 4)

A

##      [,1] [,2] [,3] [,4]
## [1,]    1    4    7   10
## [2,]    2    5    8   11
## [3,]    3    6    9   12
```

Nested Loops

```
# obtaining reciprocal of those values < 6
for (i in 1:nrow(A)) {
  for (j in 1:ncol(A)) {
    if (A[i,j] < 6) A[i,j] <- 1 / A[i,j]
  }
}

A

##            [,1] [,2] [,3] [,4]
## [1,] 1.0000000 0.25    7   10
## [2,] 0.5000000 0.20    8   11
## [3,] 0.3333333 6.00    9   12
```

Repeat Loops

Repeat Loops

repeat executes the same code over and over until a stop condition is met.

```
repeat {
  keep_doing_something
  if (stop_condition) break
}
```

The break statement stops the loops

Repeat Loops

```r
value <- 2

repeat {
  value <- value * 2
  print(value)
  if (value >= 40) break
}

## [1] 4
## [1] 8
## [1] 16
## [1] 32
## [1] 64
```

If you enter an infinite loop, break it by pressing ESC key

Repeat Loops

To skip a current iteration, use next

```
value <- 2

repeat {
  value <- value * 2
  print(value)
  if (value == 16) {
    value <- value * 2
    next
  }
  if (value > 80) break
}

## [1] 4
## [1] 8
## [1] 16
## [1] 64
## [1] 128
```

While Loops

While Loops

It can also be useful to repeat a computation until a condition is false. A while loop provides this form of control flow

```
while (condition) {
  keep_doing_something
}
```

While Loops

- `while` loops are like backward `repeat` loops;
- `while` checks first and then attempts to execute
- computations are carried out for as long as the condition is true
- the loop stops when the condition is false
- If you enter an infinite loop, break it by pressing ESC key

While Loops

```
value <- 2

while (value < 40) {
  value <- value * 2
  print(value)
}

## [1] 4
## [1] 8
## [1] 16
## [1] 32
## [1] 64
```

If you enter an infinite loop, break it by pressing ESC key

For Loops and Vectorized Computations

- R `for` loops have a bad reputation for being slow
- Experienced users will tell you to avoid for loops in R (me included)
- R provides a family of functions that tend to be more efficient than loops (i.e. `apply()` functions)

For Loops and Vectorized Computations

- For purposes of learning programming (and flow control structures in R), I won't demonize R loops
- You can start solving a problem using a for loop
- Once you solved it, try to see if you can find a vectorized alternative
- It takes practice and experience to find alternative solutions to for loops
- There are cases when using `for` loops is inevitable

Repeat, While, For

- If you don't know the number of times something will be done you can use either `repeat` or `while`
- `while` evaluates the condition at the beginning
- `repeat` executes operations until a stop condition is met
- If you know the number of times that something will be done, use `for`
- `for` needs an *iterator* and a vector of *times*

For Loop

This example is just for demo purposes (not recommended in R)

```r
# empty numeric vector
x <- numeric(0)
x

## numeric(0)

# for loop to fill x
for (i in 1:5) {
  x[i] <- i
}
x

## [1] 1 2 3 4 5
```

For Loop

If you know the number of times

```
# empty numeric vector
x <- numeric(5)
x

## [1] 0 0 0 0 0

# for loop to fill x
for (i in 1:5) {
  x[i] <- i
}
x

## [1] 1 2 3 4 5
```

Quiz Questions

- What happens if you pass NA as a condition to if()?

- What happens if you pass NA as a condition to ifelse()?

- What types of values can be passed as the first argument to the switch() function?

- How do you stop a repeat loop executing?

- How do you jump to the next iteration of a loop?
